Type of feeder (Chewing, sucking, etc.): Chewing

Host plant/s: Bluegrass, tall fescue, and Bermuda grass throughout Northern US and Southern Canada.

Description of Damage (larvae and adults): The larvae feed on bluegrass, tall fescue, and sometimes Bermuda grass, which thins lawns and produces a ragged appearance. Severely pruned plants may be killed. Early stage larvae are located within the leaf fold at the base of the plant and feed on the leaf surface. As they get older they move to the base of the plant. The females drop eggs randomly during flight, producing a spring and summer generation. Mature larvae overwinter in silk-lined tunnels in the soil or thatch. Most egg-laying occurs just after sunset. Each generation lasts 4-10 weeks depending on the temperature.
