

Pest Profile

Photo credit: By Ivy Orellana, University of Nebraska-Lincoln

Common Name: Confused Flour Beetle

Scientific Name: *Tribolium confusum* (duVal)

Order and Family: Coleoptera: Tenebrionidae

Size and Appearance: Adults are about 3-4 mm in length with a distinct reddish brown coloration. It features club-like antennae that is 4-segmented and the sides of the beetle's thorax are straight. The antennae and straight rather than curved thorax are helpful in distinguishing it from the red flour beetle, found in similar locations. Adults do have wings but are seldom seen in flight. Larvae are white, 4-5mm in length, and have a "hard bodied" appearance.

	Length (mm)	Appearance
Egg	0.1 mm in length	Clear, sticky eggs are deposited directly on food particles. Females generally lay a few a day but can produce 200-500 in her lifetime.
Larva/Nymph	4-5 mm in length depending on instar	White, wiry, and not soft. Usually 7-8 instars but can have as many as 18.
Adult	3-4 mm long	Red/brown in color, 4-segmented antennae, straight thorax.
Pupa (if applicable)	3 mm long	Pupae are similar in color to the larva, with a yellowish sheen. Distributed among grain larvae currently feeding on.

Type of feeder (Chewing, sucking, etc.): Chewing

Host food product/s: *Tribolium confusum* feeds on whole kernels of grain and has a strong preference for undamaged product such as peas, beans, nuts, and fruits. Occasionally will feed on museum specimens, pharmaceuticals, chocolate, and pepper.

Description of Damage (larvae and adults): Confused flour beetles leave a noticeable scent behind as they feed, particularly if population is high. This can also impact the taste, making it unfit for human consumption.
